Practical Padding Oracle Attacks

2 / 41

Outline

Introduction

- Review of CBC Mode
- Padding Oracle attack
- 2 Finding padding oracles
 - Find potential padding oracles
 - Confirm the existence of padding oracles
- 3 Basic PO attacks
 - Cracking CAPTCHA
 - Decrypting JSF view states

4 Advanced PO attacks

- Using PO to encrypt
- Distributed cross-site PO attacks

- CBC mode is a cryptography mode of operation for a block cipher.
- Allows encryption of arbitrary length data.
- Encryption and decryption are defined by:

$$C_i = e_K(P_i \oplus C_{i-1})$$

$$P_i = d_K(C_i) \oplus C_{i-1}$$

Juliano Rizzo, Thai Duong ()

Typical block size *n*: 64 bits (DES, triple DES) or 128 bits (AES).

Typical key size: 56 bits (DES), 168 bits (triple DES), 128, 192 or 256 bits (AES).

Review of CBC Mode

Padding

3

• First introduced by Vaudenay at Eurocrypt 2002.

• Two assumptions:

- Adversary can intercept padded messages encrypted in CBC mode.
- Adversary has access to a padding oracle.

Padding oracle attack

What is a padding oracle?

Juliano Rizzo, Thai Duong ()

Practical Padding Oracle Attacks

BH Europe 2010

- < ∃ →

A.

8 / 41

Padding oracle attack What is a padding oracle?

• Adversary submits a CBC mode ciphertext C to oracle d.

- Oracle decrypts under fixed key K and checks correctness of padding.
- Oracle outputs VALID or INVALID according to correctness of padding:

$$\eth(C) = \begin{cases} 0, & \text{invalid} \\ 1, & \text{valid} \end{cases}$$

Finding potential padding oracles Blackbox testing

• Crawl the target to find BASE64 strings that look like a ciphertext.

- Replace a byte in the last block of the ciphertext by a random value, and send to the target.
- See if there is any error message. Even a blank page is enough information.

- Want to write your own tool to detect padding oracle? Follow this guideline (which is based on the algorithm in slide 22):
 - Determine the block size *b*.
 - Pick a few random words $r_1, ..., r_b$, and take i = 0.
 - Pick $r = r_1 r_2 ... r_{b-1} (r_b \oplus i)$.
 - Send r|y to the target, where y is a valid ciphertext block. Record the value of *i*, content length, and content type of the response. Increment *i*, and go back to step 3 until *i* > 255.
 - Now you have 256 responses. If all of them are the same, then the target is not easily showing you that it is vulnerable to padding oracle attack.
 - Otherwise, look at each value of *i* where the responses are different from the rest. Examine carefully each response to see what happened.

Decrypting JSF view states Padding oracle in JSF frameworks

By default, all JSF frameworks would display a very detailed error message if it fails to decrypt a view state.

Decrypting JSF view states Padding Oracle in JSF frameworks

• Most JSF frameworks allow developers to turn off error messages. Then we can use the following simple trick:

Padding oracle in JSF frameworks when error-page is turned off

- Say we want to decrypt block C_i of an encrypted view state $C_0|C_1|...|C_{n-1}$, then we send $C_0|C_1|...|C_{n-1}|C_{random}|C_i$ to the target.
- Since Java ignores those extra blocks while decrypting and deserializing view states, it's VALID padding if the target returns the same page as when the view state is unaltered.
- And it's probably INVALID padding if we see something else, e.g. a HTTP 500 error message.

Using PO to encrypt An introduction to CBC-R

• CBC-R turns a decryption oracle into an encryption oracle.

• We all know that CBC decryption works as following:

$$P_i = d_K(C_i) \oplus C_{i-1}$$

$$C_0 = IV$$

• We can use a padding oracle to get $d_{\mathcal{K}}(C_i)$, and we control C_{i-1} . In other words, we can produce any P_i as we want.

- CBC-R allows us to encrypt any message, but if we cannot set the *IV*, then first plaintext block *P*₀ will be random and meaningless.
- If the victim expects the decrypted message to start with a standard header, then it will ignore the forged message constructed by CBC-R.
- We have not found generic way to overcome this limitation. However, we have found workarounds for particular cases.

Using captured ciphertexts as prefix

•
$$P_{valid} = d_K (C_{captured} | IV_{CBC-R} | P_{CBC-R}).$$

- The block at the position of *IV_{CBC-R}* is still garbled.
- We can make the garbled block becomes part of some string that doesn't affect the semantic of the message such as comment or textbox label.

Using captured ciphertexts as prefix

- $P_{valid} = d_K(C_{captured}|IV_{CBC-R}|P_{CBC-R}).$

Brute-forcing C_0

• CBC-R can produce many different ciphertexts that decrypted to the same plaintext block chain $P_{n-1}, ..., P_1$. The only difference is the first plaintext block which is computed as following:

$$P_0 = d_K(C_0) \oplus IV$$

- A valid header means that the first few bytes of P₀ must match some magic numbers. There are also systems that accept a message if the first byte of its P₀ matches its size.
- If this is the case, and if the message is short enough, we can try our luck by brute-forcing C₀.
